Abstract

The successful comprehension of a utility conditional (i.e., an ‘*if p, then q*’ statement where *p* and/or *q* is valued by one or more agents) requires the construction of a mental representation of the situation described by that conditional, and integration of this representation with prior context. In an eye-tracking experiment, we examine the time course of integrating conditional utility information into the broader discourse model. Specifically, the experiment determines whether readers are sensitive during rapid heuristic processing to the congruency between the utility of the consequent clause of a conditional (positive or negative) and a reader’s subjective expectations based on prior context. On a number of eye-tracking measures we find that readers are sensitive to conditional utility; conditionals for which the consequent utility mismatches that which would be anticipated on the basis of prior context result in processing disruption. Crucially, this sensitivity emerges on measures which are accepted to indicate early processing within the language comprehension system, and suggests that the evaluation of a conditional’s utility informs the early stages of conditional processing.

### Introduction

Conditionals of the form of the form *if p then q* are often asserted with the goal of influencing the behaviour of others (Evans, Neilens, Handley, & Over, 2008). A conditional promise (e.g., *if you help me fix my car, then I will buy you a beer*) is often uttered with the intent of *encouraging* a behaviour while a conditional threat (e.g., *if you scratch my car, I'll ground you*) is often uttered with the intent of *discouraging* a behaviour. These are two examples from a range of assertions that fall under the umbrella of *utility conditionals* (Bonneton, 2009; Bonneton, Haigh & Stewart, 2013). Broadly defined, utility conditionals are conditional statements with some degree of utility to one or more agents (e.g., the speaker, the hearer or someone else).

Bonneton (2009) defines utility in terms of goal achievement, with an action that helps an agent to achieve a desired goal having positive utility for that agent (and vice versa for actions that hinder goal achievement). This descriptive approach to representing conditionals is largely unconcerned with speech act labels, but is nevertheless compatible with a narrower algorithmic approach specifically designed for classifying conditional promises, tips, threat and warnings (López-Rousseau & Ketelaar, 2004; 2006). This two-stage Pragmatic Cues Algorithm uses speaker control of the consequent event (control or no control) and the subjective utility of this event (positive or negative) as cues to discriminate between conditional promises, tips, threats and warnings with over 90% accuracy (see Figure 1).

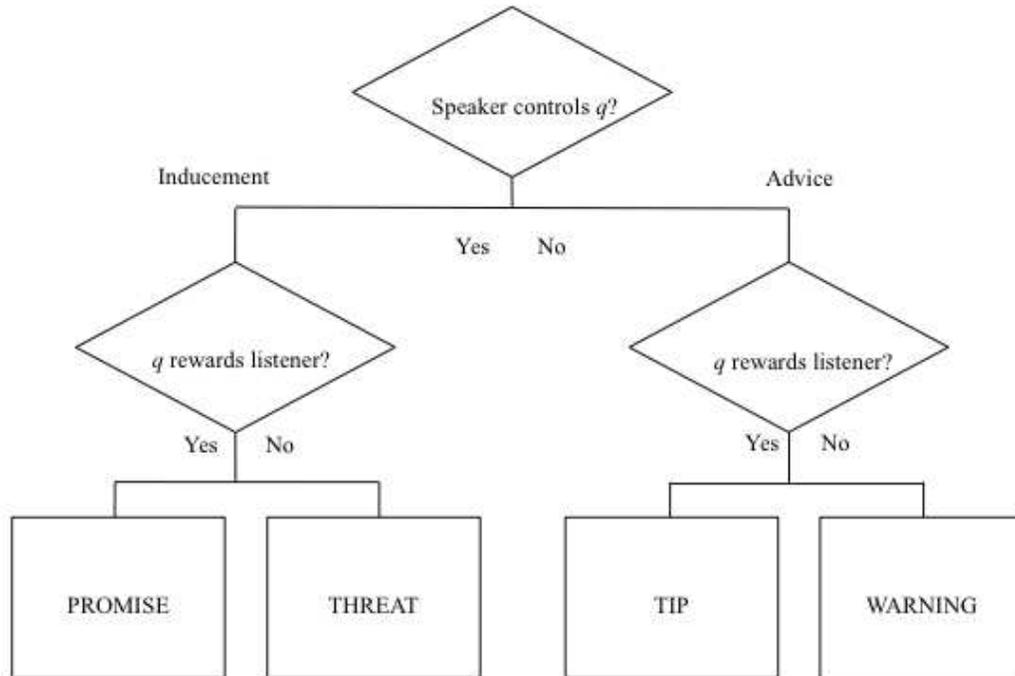

Figure 1: Pragmatic Cues Algorithm (López-Rousseau and Ketelaar, 2006).

While the theories above have been developed using data from tasks in which participants are asked to consciously rate or classify conditionals, a more recent line of research has sought to examine how conditionals are processed spontaneously during incremental comprehension (Haigh, Stewart, Wood, & Connell, 2011; Ferguson & Sanford, 2008; Nieuwland, 2013; Nieuwland & Martin, 2012; Stewart, Haigh, & Ferguson, in press; Stewart, Haigh, & Kidd, 2009). The goal of this approach is to identify the fast acting heuristics that guide the early stages of conditional processing. Dual-processing accounts of cognition (e.g., Evans, 1989, 2003) provide a possible theoretical framework in which the operation of these fast acting heuristics may be conceptualised. These accounts distinguish between rapid, automatic heuristic

processing, and slower, more effortful analytic processing (see Evans, 2008 for a detailed review).

Following the Pragmatic Cues Algorithm (López-Rousseau & Ketelaar, 2004, 2006), two possible cues that may inform the processing of conditionals are those driven by speaker control and utility. Speaker control and utility are central to this account and, given their salience, are obvious candidates for rapidly informing the early heuristic interpretation of a conditional speech act as it is comprehended. Indeed there is evidence that both these cues can be used in the processing of conditional indirect meaning *downstream* from the conditional itself (Haigh et al., 2011). Further evidence for the importance of utility in the context of conditionals can be found in Evans et al. (2008). They examined the circumstances under which conditionals can be asserted, and reported that conditional utility is central for the assertability of a conditional promise. In two experiments they found that utility (alongside the conditional link from p to q) played a key role in people's judgments of the persuasiveness of a particular conditional. Together, the Pragmatic Cues Algorithm and the empirical findings reported above suggest that utility is central to how conditionals are used and understood in everyday situations; however, the question of *when* the influence of utility is manifested during online conditional processing remains open.

There is evidence that the first cue in the Pragmatic Cues Algorithm, speaker control, can influence the early stages of conditional processing. Stewart et al. (in press) recorded eye movements as participants read conditional promises or tips embedded in vignettes (e.g., 'if you submit your paper to the Journal of Physics, then I will publish it in the next issue' / 'if you submit your paper to the Journal of Physics, then it stands a

good chance of being published'). Prior context was manipulated so that the character asserting the conditional either had perceived control of the consequent event (e.g., the Journal's Editor) or no control of this event (e.g., a colleague). The eye movement record revealed early disruption to processing occurring as the consequent clause was read when a promise was uttered by a protagonist with no control over the consequent event.

In the experiment below, we examine whether perceived utility (the second pragmatic cue in the Pragmatic Cues Algorithm) is also able to influence the early processing of conditionals. Finding evidence that readers are sensitive online to conditional utility (and the extent to which it (mis)matches information provided by prior discourse) would be compatible with a view in which conditional utility plays a key role in the fast-acting heuristics that operate during the early stages of conditional processing. We can manipulate the degree to which consequent utility is congruent with a reader's expectations by varying prior context to set up the likelihood that the subsequent conditional utility will be positive or negative. In Example 1, below, the conditional describes an event where the editor of a journal is either impressed or unimpressed by the findings reported by the character "Alan". In the case where the editor is *impressed* by Alan's findings (a1), this positive view will result in the anticipation of a subsequent positive utility action by the Editor (i.e., an action that is likely to help Alan achieve his goal of publishing the findings). However, for the case where the editor is *unimpressed* by Alan's findings (a2), this will result in the expectation of negative utility for Alan. The conditional statement uttered by the Editor then describes either a negative (b1) or a positive (b2) action for the hearer, Alan. The degree to which the anticipated utility (as

determined by prior context) and actual utility of the conditional match results in variation in the degree to which the conditional is congruent with prior context.

Example 1:

*Alan had just presented his research paper to a meeting of leading physicists. During the coffee break he was called over by the Editor of the internationally renowned Journal of Physics.*

*(a1) The Editor was very impressed by Alan's findings and said that they should be widely publicised*

*(a2) The Editor was very critical of Alan's findings and said that they were not valid.*

*(b1) As they parted, the Editor told Alan "if you submit your paper to the Journal of Physics, then I will reject it outright".*

*(b2) As they parted, the Editor told Alan "if you submit your paper to the Journal of Physics, then I will accept it outright".*

*This comment made Alan consider his options carefully.*

\*Example adapted from Evans (2005).

It should be noted that in terms of language processing, finding a plausibility effect such that descriptions of implausible events (i.e., sentences incongruent with prior context) take longer to read than descriptions of plausible (i.e., congruent) events would not be considered particularly noteworthy (see Rayner, Warren, Juhasz, & Liversedge, 2004).

However, it is important to emphasise that we are using such an effect here *diagnostically* to explore how conditionals themselves are processed. Plausibility, in the case of our

conditionals, is determined by the degree of match between the utility associated with a particular conditional and prior context (which varied due to a controlled polarity manipulation of the protagonist's attitude). Any perceived implausibility is likely to be based on real world knowledge about what might typically happen in a situation where the Editor likes or dislikes a paper. Therefore, evidence of a plausibility effect on the processing of conditionals that emerges rapidly would be supportive of a view of conditional processing in which utility plays an important early (heuristic) role in how conditionals are processed and understood.

In the experiment below we use eye-tracking during the comprehension of conditionals to explore this question of time course. We use this technique because eye-tracking can tell us *when* it is during the processing of conditionals that conditional utility comes to exert an influence. Early effects of utility (e.g., occurring on first-pass regressions out and regression path measures of the consequent clause) would be indicative of this variable being involved in rapid heuristic processing, whereas delayed effects (e.g., only on total reading time for the consequent clause or delayed effects emerging only in subsequent regions of text) would indicate that the consideration of utility is associated with slower, more cognitively demanding analytic processes.

### Experiment

In the experiment that follows we consider the Pragmatic Cues Algorithm (López-Rousseau & Ketelaar, 2004, 2006) as a processing framework. If readers are sensitive to the utility of the consequent clause of a conditional as the conditional is read, then there should be a processing disruption for situations in which the consequent utility

*mismatches* that which a reader would anticipate on the basis of prior context. Based on previous evidence from eye-movement research (e.g., Braze, Shankweiler, Ni, & Palumbo, 2002; Ni, Fodor, Crain & Shankweiler, 1998; Rayner, et al., 2004, Stewart, Pickering, & Sturt, 2004), we expect this disruption to be exhibited as an early slow-down in reading (e.g., on first-pass regressions out and regression path measures), with an increased incidence of regressive eye movements during processing of the consequent analysis region. In contrast, if initial processing of a conditional does not involve the evaluation of consequent utility, then we could expect to find no sensitivity to utility mismatches during early processing of a conditional itself, but rather an effect emerging on measures of later processing (e.g., total reading times) or on measures associated with a subsequent post critical region of text.

### Method

#### *Participants*

Thirty six native English speakers from the University of Kent took part, in return for course credit.

#### *Design & Materials*

Experimental items consisted of conditional statements embedded in fictional vignettes. Prior context was manipulated to bias the *anticipated* utility of the subsequent conditional to be either positive or negative. Additionally, the *actual* utility of the conditional statement was manipulated to be either positive or negative. This resulted in a fully-crossed 2 (Anticipated Utility) x 2 (Actual Utility) repeated measures design comparing

four conditions: (i) Anticipate Positive / Actual Positive; (ii) Anticipate Positive / Actual Negative; (iii) Anticipate Negative / Actual Positive; and (iv) Anticipate Negative / Actual Negative. Note that the conditional statement was lexically identical in conditions (i) and (iii) (where Actual Utility is Positive) and conditions (ii) and (iv) (where Actual Utility is Negative).

Thirty two experimental vignettes were constructed as in Table 1 below (see Appendix for full set of items). Each vignette was five sentences long. Sentence one introduced a protagonist (e.g., Alan). Sentence two introduced a character who would later assert the conditional statement (e.g., the Editor). Sentence three was manipulated so that it biased the anticipated utility of the subsequent conditional to be either positive or negative for the protagonist (e.g. ‘*The Editor was impressed/critical of Alan’s findings...*’). Sentence four contained a conditional statement that was manipulated to be either positive or negative for the protagonist (e.g. ‘*...I will accept/reject the paper outright*’). Sentence five provided a neutral continuation for analysis of spillover effects, and was identical across all four conditions.

Table 1: Example item showing regions of analysis.

*Anticipate Positive / Actual Positive*

Alan had just presented his research paper to a meeting of leading physicists. During the coffee break he was called over by the Editor of the internationally renowned Journal of Physics. The Editor was very impressed by Alan’s findings and said that they should be widely publicised. As they parted, the Editor told Alan |“if you submit your paper to the Journal of Physics, PRE-CRITICAL|then I will accept it outright”. CRITICAL|This comment made Alan consider his options carefully. POST-CRITICAL|

*Anticipate Positive / Actual Negative*

Alan had just presented his research paper to a meeting of leading physicists. During the coffee break he was called over by the Editor of the internationally renowned Journal of

Physics. The Editor was very impressed by Alan's findings and said that they should be widely publicised. As they parted, the Editor told Alan ["if you submit your paper to the Journal of Physics, PRE-CRITICAL|then I will reject it outright". CRITICAL|This comment made Alan consider his options carefully. POST-CRITICAL|

*Anticipate Negative / Actual Positive*

Alan had just presented his research paper to a meeting of leading physicists. During the coffee break he was called over by the Editor of the internationally renowned Journal of Physics. The Editor was very critical of Alan's findings and said that they were not valid. As they parted, the Editor told Alan ["if you submit your paper to the Journal of Physics, PRE-CRITICAL|then I will accept it outright". CRITICAL|This comment made Alan consider his options carefully. POST-CRITICAL|

*Anticipate Negative / Actual Negative*

Alan had just presented his research paper to a meeting of leading physicists. During the coffee break he was called over by the Editor of the internationally renowned Journal of Physics. The Editor was very critical of Alan's findings and said that they were not valid. As they parted, the Editor told Alan ["if you submit your paper to the Journal of Physics, PRE-CRITICAL|then I will reject it outright". CRITICAL|This comment made Alan consider his options carefully. POST-CRITICAL|

The full set of experimental items were split into four Latin-square presentation lists, with each list containing 32 experimental items, eight in each of the four conditions. Experimental items in each list were interspersed randomly among 38 unrelated filler vignettes, with each participant seeing a different random order. Importantly, each participant only saw each target sentence once, in one of the four conditions. Nine participants were randomly assigned to read each list. Comprehension questions followed half of the experimental and half of the filler trials. Participants did not receive feedback for their responses to these questions and all scored at or above 90% accuracy.

*Procedure*

Eye movements were recorded using an Eyelink 1000 eye-tracker in the Desktop Mount configuration. Viewing was binocular and recordings of gaze location and movement

were sampled from the left eye at 1000 Hz. A chin and forehead rest was used to stabilise the participants' head position. Vignettes were presented in size 14 Arial font on a CRT monitor, 60 centimetres from the participants' eyes.

At the start of the experiment, the eye-tracker was calibrated and validated against nine fixation points to establish the correlation between x/y voltages and screen position. This procedure was repeated as necessary during the experiment. Participants were instructed to read at their normal rate for comprehension. Before each trial the screen was blank except for the presence of a gaze trigger, which was located at the top left of the screen- where the first character of the text would be displayed. Participants' accurate fixation on this gaze trigger automatically initiated the next trial presentation. After reading each sentence, participants clicked a button on the mouse that either led to the presentation of a comprehension question (after 50% of trials) or the next trial.

## Results

### *Method of analysis*

Reading patterns were analysed in three regions, as shown in Table 1. The critical analysis region was the consequent clause of the conditional statement (e.g. 'then I will accept/reject it outright'). This region was lexically identical for the two conditions that described a positive actual utility, and the two conditions that described a negative actual utility. We also analysed a pre-critical region (the antecedent clause) and a post-critical region (sentence five), both of which were lexically identical across all four conditions.

An automatic procedure pooled fixations shorter than 80 msec. with adjacent fixations, excluded fixations that were shorter than 40 msec. if they were not within three

characters of another fixation and truncated fixations longer than 1200 msec. Trials in which two or more adjacent regions had zero first-pass reading time were removed.

These trials accounted for less than 1% of the total data set.

We analysed five processing measures. The first three provide information about early processing as a region of text is initially encountered (1-3) and the final two account for later processes as a region of text is revisited (4-5). Table 2 displays mean values for each measure in each condition and region. Figure 2 displays the mean first-pass regressions out from the pre-critical, critical and post-critical regions, while Figure 3 displays the mean regression path reading times for the same analysis regions.

1. *First-pass reading time* is the sum of all the fixation durations (msec.) from first entering the region until first exiting to the left or right.
2. *First-pass regressions out* is the percentage of trials in which regressive saccades were made from the current most rightward fixation into an earlier region. This measure indicates the degree to which left to right eye movements are disrupted while first reading a region of text.
3. *Regression path reading time* is the sum of all fixation durations (msec.) from first entering a region until first exiting the region to the right (including all regressions). This is a measure of how long it takes reader to *go past* a region of text after first entering it.
4. *Regressions in* is the percentage of trials where one or more fixations in a region are preceded by a fixation in a later region. This provides information about which regions of text needed to be re-visited.
5. *Total reading time* is the sum of all fixation durations in a region (msec.).

Table 2: Mean reading times and regressions to each region (standard errors in parentheses).

Anticipated / Actual Utility	First-pass (msec.)	First-pass Regressions Out %	Regression Path (msec.)	Regressions In %	Total Time (msec.)
<i>Pre-Critical Region</i>					
Anticipated + / Actual +	546 (30)	14.5 (2.3)	757 (58)	19.2 (3.1)	732 (32)

Anticipated – / Actual –	1729 (77)	43.1 (5.1)	2630 (178)	n/a	1989 (87)

Analysis of the eye movement data in each region was performed using 2 x 2 (Anticipated Utility x Actual Utility) repeated measures ANOVAs, with subjects ( $F_1$ ) and items ( $F_2$ ) as random factors.

*Pre-critical Region*

On first-pass reading times, the ANOVA revealed no significant main effects for Anticipated Utility ( $F_s < 1$ ) nor Actual Utility ( $F_s < 1$ ) and no significant interaction between these variables ( $F_1(1, 35) = 2.67, p = .112, \eta_p^2 = .07; F_2(1, 31) = 1.94, p = .17, \eta_p^2 = .06$ ).

The ANOVA on first-pass regressions out revealed no significant main effects of Anticipated Utility ( $F_s < 1$ ) or Actual Utility ( $F_s < 1$ ) and no significant interaction between these variables ( $F_1(1, 35) = 1.52, p = .23, \eta_p^2 = .04; F_2(1, 31) = 1.79, p = .19, \eta_p^2 = .06$ ).

On regression path reading times, the ANOVA revealed no main effects of Anticipated Utility ( $F_1(1, 35) = 1.04, p = .31, \eta_p^2 = .029; F_2(1, 31) = 1.29, p = .26, \eta_p^2 = .04$ ) or Actual Utility ( $F_1(1, 35) = 1.03, p = .32, \eta_p^2 = .029; F_2 < 1$ ) and no interaction between these variables ( $F_s < 1$ ).

On regressions in, the ANOVA revealed no main effects of Anticipated or Actual Utility ( $F_s < 1$ ). However the interaction between these variables was significant ( $F_1(1, 35) = 32.85, p < .001, \eta_p^2 = .48; F_2(1, 31) = 35.39, p < .001, \eta_p^2 = .53$ ). Pairwise comparisons revealed that there were fewer regressions into this region for positive utility conditionals when readers anticipated positive utility than when they anticipated negative utility ( $t_1(35) = 4.61, p < .001; t_2(31) = 4.93, p < .001$ ). For negative utility conditionals there were fewer Regressions In when readers anticipated negative utility than when they anticipated positive utility ( $t_1(35) = 3.88, p < .001; t_2(31) = 3.97, p < .001$ ).

On total reading times, the ANOVA revealed no main effects of Anticipated Utility ( $F_s < 1$ ) or Actual Utility ( $F_1(1, 35) = 1.59, p = .22, \eta_p^2 = .04; F_2(1, 31) = 1.33, p$

= .26,  $\eta_p^2 = .04$ ). However, the interaction between these variables was significant ( $F_1(1, 35) = 32.79, p < .001, \eta_p^2 = .48$ ;  $F_2(1, 31) = 28.45, p < .001, \eta_p^2 = .48$ ). Pairwise comparisons revealed the total time spent reading positive utility conditionals was shorter when the context anticipated a positive utility than when it anticipated a negative utility ( $t_1(35) = 4.54, p < .001$ ;  $t_2(31) = 4.30, p < .001$ ). In contrast, for negative utility conditionals, total reading times were shorter when the preceding context anticipated a negative utility than when it anticipated a positive utility ( $t_1(35) = 5.17, p < .001$ ;  $t_2(31) = 3.73, p = .001$ ).

### *Critical Region*

On first-pass reading times, the ANOVA revealed no main effects of Anticipated Utility ( $F_s < 1$ ) or Actual Utility ( $F_1(1, 35) = 3.91, p = .056, \eta_p^2 = .10$ ;  $F_2(1, 31) = 1.29, p = .27, \eta_p^2 = .04$ ). However, the interaction between Anticipated and Actual utility variables was significant by subjects and marginal by items ( $F_1(1, 35) = 4.95, p = .03, \eta_p^2 = .12$ ;  $F_2(1, 31) = 3.71, p = .06, \eta_p^2 = .11$ ). Pairwise comparisons were non-significant, but indicated a numerical trend, whereby first-pass reading times for positive utility conditionals were faster when readers anticipated positive utility than when they anticipated negative utility ( $t_1(35) = 1.18, p = .25$ ;  $t_2(31) = 0.95, p = .35$ ). In contrast, for negative utility conditionals, first-pass reading times were faster when readers anticipated negative utility than when they anticipated positive utility ( $t_1(35) = 1.85, p = .07$ ;  $t_2(31) = 1.99, p = .06$ ).

The ANOVA on first-pass regressions out revealed there were no main effects of Anticipated Utility ( $F_1 < 1$ ;  $F_2(1, 31) = 1.13, p = .30, \eta_p^2 = .04$ ) or Actual Utility ( $F_s < 1$ ). However, the interaction between these variables was significant ( $F_1(1, 35) = 13.76, p =$

.001,  $\eta_p^2 = .28$ ;  $F_2(1, 31) = 25.79, p < .001, \eta_p^2 = .45$ ). Pairwise comparisons revealed that there were fewer first-pass regressions out for positive utility conditionals when readers anticipated positive utility than when they anticipated negative utility ( $t_1(35) = 3.55, p = .001$ ;  $t_2(31) = 4.28, p < .001$ ). For negative utility conditionals there were fewer first-pass regressions out when readers anticipated negative utility than when they anticipated positive utility ( $t_1(35) = 2.01, p = .052$ ;  $t_2(31) = 2.15, p = .039$ ).

On regression path reading times, the ANOVA revealed no main effects of Anticipated or Actual Utility ( $F_s < 1$ ); however the interaction between these variables was significant ( $F_1(1, 35) = 15.06, p < .001, \eta_p^2 = .30$ ;  $F_2(1, 31) = 23.37, p < .001, \eta_p^2 = .43$ ). Pairwise comparisons revealed that regression path reading times for positive utility conditionals were faster when readers anticipated positive utility than when they anticipated negative utility ( $t_1(35) = 2.32, p = .026$ ;  $t_2(31) = 3.62, p = .001$ ). For negative utility conditionals regression path reading times were faster when readers anticipated negative utility than when they anticipated positive utility ( $t_1(35) = 4.16, p < .001$ ;  $t_2(31) = 3.76, p = .001$ ).

On regressions in, ANOVA revealed no significant main effects of anticipated or actual utility ( $F_s < 1$ ). However the interaction between these variables was significant ( $F_1(1, 35) = 16.81, p < .001, \eta_p^2 = .32$ ;  $F_2(1, 31) = 12.25, p = .001, \eta_p^2 = .28$ ). Pairwise comparisons revealed that there were fewer regressions into this region for positive utility conditionals when readers anticipated positive utility than when they anticipated negative utility ( $t_1(35) = 2.79, p = .009$ ;  $t_2(31) = 2.74, p = .01$ ). For negative utility conditionals there were fewer Regressions In when readers anticipated negative utility than when they anticipated positive utility ( $t_1(35) = 3.06, p = .004$ ;  $t_2(31) = 2.27, p = .03$ ).

On total reading times, the ANOVA revealed no main effects of Anticipated Utility ( $F_1(1, 35) = 1.33, p = .26, \eta_p^2 = .04; F_2 < 1$ ) or Actual Utility ( $F_1(1, 35) = 2.60, p = .12, \eta_p^2 = .07; F_2 < 1$ ). However, the interaction between these variables was significant ( $F_1(1, 35) = 66.98, p < .001, \eta_p^2 = .66; F_2(1, 31) = 88.23, p < .001, \eta_p^2 = .74$ ). Pairwise comparisons in these regions revealed that the total time spent reading positive utility conditionals was shorter when the context anticipated a positive utility than when it anticipated a negative utility ( $t_1(35) = 6.56, p < .001; t_2(31) = 5.12, p < .001$ ). In contrast, for negative utility conditionals, total reading times were shorter when the preceding context anticipated a negative utility than when it anticipated a positive utility ( $t_1(35) = 6.52, p < .001; t_2(31) = 5.45, p < .001$ ).

#### *Post-critical region*

On first-pass reading times, the ANOVA showed a main effect of Anticipated Utility that was significant by subjects and marginal by items ( $F_1(1, 35) = 5.70, p = .02, \eta_p^2 = .14; F_2(1, 31) = 3.91, p = .06, \eta_p^2 = .11$ ). First-pass reading times were longer when the context anticipated a negative utility, compared to when it anticipated a positive utility. There was no significant main effect of Actual Utility ( $F_s < 1$ ). The interaction between these two variables was significant by subjects only ( $F_1(1, 35) = 4.59, p = .039, \eta_p^2 = .12; F_2(1, 31) = 3.35, p = .08, \eta_p^2 = .10$ ). First-pass reading times on negative utility conditionals were faster when readers anticipated negative utility than when they anticipated positive utility ( $t_1(35) = 3.14, p = .003; t_2(31) = 2.84, p = .008$ ), but there was no difference in reading times between the two positive utility conditionals ( $t_1(36) = 0.36, p = .23; t_2(31) = 0.29, p = .77$ ).

The ANOVA on first-pass regressions out revealed no significant main effects of Anticipated Utility or Actual Utility ( $F_s < 1$ ), but a significant interaction between these variables ( $F_1(1, 35) = 18.21, p < .001, \eta_p^2 = .34; F_2(1, 31) = 16.96, p < .001, \eta_p^2 = .35$ ). Pairwise comparisons showed that there were fewer first-pass regressions out for positive utility conditionals when readers anticipated positive utility than when they anticipated negative utility ( $t_1(35) = 3.00, p = .005; t_2(31) = 2.70, p = .01$ ). For negative utility conditionals there were fewer first-pass regressions out when readers anticipated negative utility than when they anticipated positive utility ( $t_1(35) = 3.28, p = .002; t_2(31) = 2.96, p = .006$ ).

On regression path reading times, the ANOVA revealed no main effect of Anticipated Utility ( $F_s < 1$ ), a main effect of Actual Utility that was significant by participants only ( $F_1(1, 35) = 7.98, p = .008, \eta_p^2 = .19; F_2(1, 31) = 3.49, p = .071, \eta_p^2 = .11$ ) and an interaction between these two variables ( $F_1(1, 35) = 22.52, p < .001, \eta_p^2 = .39; F_2(1, 31) = 32.36, p < .001, \eta_p^2 = .51$ ). Pairwise comparisons revealed the same pattern of effects as in the critical region with faster regression path reading times for positive utility conditionals when readers anticipated positive utility than when they anticipated negative utility ( $t_1(35) = 3.61, p = .001; t_2(31) = 4.52, p < .001$ ). For negative utility conditionals Regression Path times were faster when readers anticipated negative utility than when they anticipated positive utility ( $t_1(35) = 4.40, p < .001; t_2(31) = 3.93, p < .001$ ).

On total reading times, the ANOVA revealed no main effects of Anticipated or Actual Utility ( $F_s < 1$ ). However, there was an interaction between these variables ( $F_1(1, 35) = 11.85, p = .002, \eta_p^2 = .25; F_2(1, 31) = 10.83, p = .002, \eta_p^2 = .26$ ). Pairwise

comparisons revealed shorter total reading times in this region for positive utility conditionals when the context anticipated positive utility than when it anticipated negative utility ( $t_1(35) = 2.72, p = .01$ ;  $t_2(31) = 2.93, p = .006$ ). For negative utility conditionals, there was a trend for faster reading times when the context anticipated negative utility compared to when it anticipated positive utility, but this difference did not reach significance here ( $t_1(35) = 1.83, p = .075$ ;  $t_2(31) = 1.77, p = .086$ ).

**Figure 2:** Mean first-pass regressions out from the pre-critical, critical and post-critical regions. Error bars show standard errors.

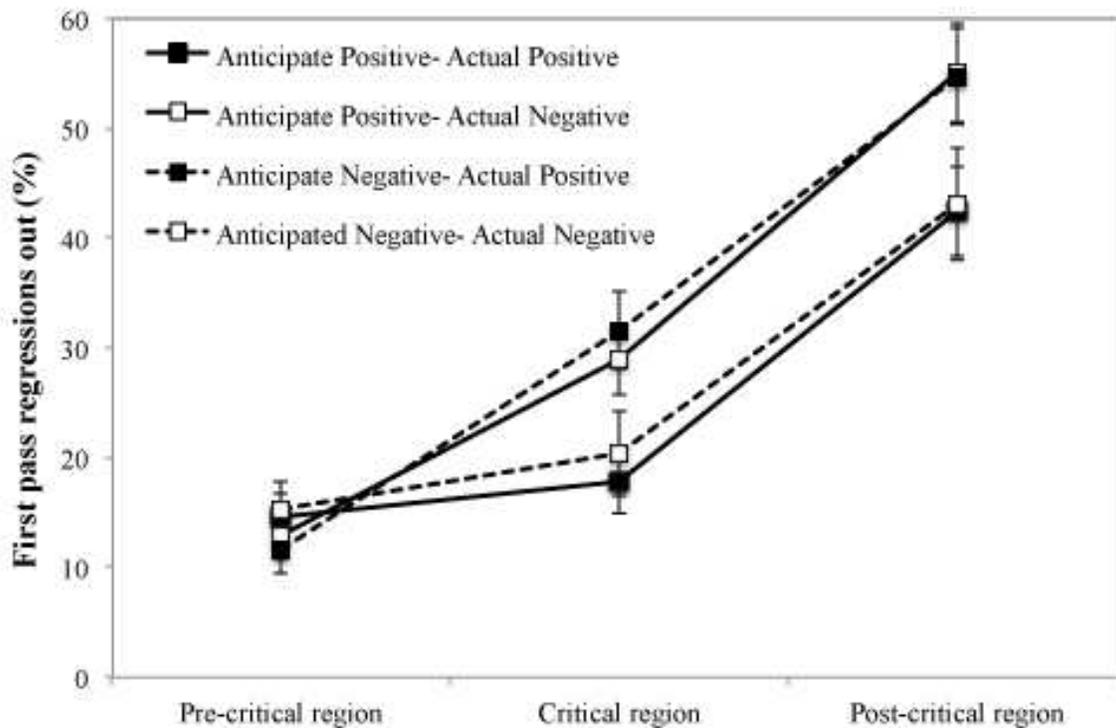

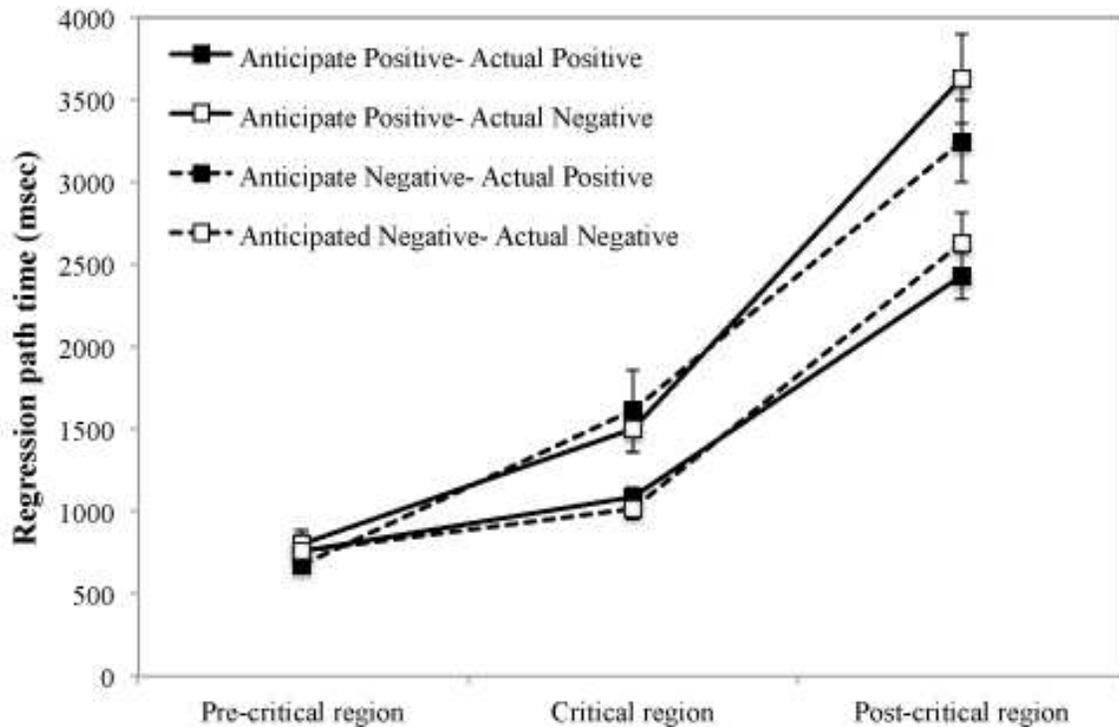

Figure 3: Mean regression path reading times for the pre-critical, critical and post-critical regions. Error bars show standard errors.

### Discussion

Our goal in this experiment was to determine at what point during comprehension readers are sensitive to the utility associated with conditional statements; critically we wanted to determine whether utility exerted its influence during rapid, heuristic driven processing or during later, delayed analytic processing. We did this by examining eye movements as participants read utility conditionals that either matched or mismatched the utility anticipated by prior context. There was some suggestion of a sensitivity to whether anticipated and actual utilities matched in the first pass reading time analysis for the critical region. As first-pass reading times are widely accepted to index early processing, this pattern would suggest that the utility associated with a conditional begins to be

evaluated relatively quickly during interpretation. Furthermore this effect (indicated by the interaction between anticipated and actual utility) was statistically robust in the critical region on measures of first-pass regressions out, regressions in, regression path and total reading times. First-pass regressions out and regression path times also reflect early processing so together these results can be seen as converging evidence in support of the view that conditional utility has a rapid influence on incremental processing (in line with the heuristic view). In the first-pass regressions out, the regressions in, the regression path and total reading times analyses, processing disruption (i.e., an increase in reading times or an increase in regressions) arose when there was a mismatch between the anticipated and actual utilities associated with the critical region of the conditional. Virtually identical effects were also found for the analyses associated with the post-critical region (apart from on the regressions in measure which does not apply for the final region of text). The persistence of this pattern of effects indicates a general (and long-lasting) disruption to interpretation when the utility of the conditional and a reader's expectations about likely utility mismatch. This is compatible with the view that utility rapidly influences heuristic-level processing, but also has a sustained influence on subsequent processing. It should be noted that while we can conclude that our data support the view that utility informs processing *rapidly*, we are not making the stronger claim that our data show that utility informs processing *immediately*. Our critical analysis region was several words long so it may be the case that within this region (even though it was short) it might have been the case that utility information came to inform processing towards the region's conclusion.

The Pragmatic Cues Algorithm (López-Rousseau & Ketelaar, 2004, 2006) was originally developed to allow for the classification of conditional speech acts that varied along the dimensions of speaker control and reward (i.e., utility). Utility is also central to Bonnefon's account of conditionals (Bonnefon, 2009) and plays a key role in the persuasiveness of conditionals (Evans et al, 2008). On the basis of the eye-tracking data we report it appears that utility plays an important early role in how conditionals are comprehended online. It could be argued that this relates to the extent of the salience associated with conditional utility. As Evans et al. found, utility plays a particularly important role in terms of how persuasive a conditional is seen as being. Given the importance of utility then in terms of trying to encourage/discourage someone's behaviour, it seems natural then to think that utility should be a source of information that is relatively easy to recover from the input when a conditional is encountered.

Bonnefon's (2009) framework, in its current form, captures utility as being simply positive, negative or neutral. As Bonnefon himself notes (p. 902), there are undoubtedly differences in utility magnitude present in conditionals when applied to real world situations. For instance, the consequent utility of the conditional *If I win the competition, then I will receive one million pounds* is higher than the consequent utility for the conditional *If I win the competition, then I will receive one thousand pounds* (although both utilities are positive). Understanding whether these magnitude differences are captured during online processing is a potential additional line of future investigation.

In addition to evidence that readers are sensitive online to the presuppositions that are communicated by conditionals describing counterfactual events (Stewart et al., 2009), to the implicit speech acts communicated by conditionals (Haigh et al., 2011) and to the

extent to which a speaker has control over the consequent event in a conditional promise (Stewart et al., in press) the research reported above demonstrates that readers are *also* sensitive to key information related to the utility associated with conditionals. The evidence presented here demonstrates that this utility information plays a rapid role in the comprehension of conditional utterances; this is compatible with utility informing fast-acting heuristic-level conditional processing. Together, these findings suggest that the successful comprehension of conditionals describing hypothetical situations requires readers to engage in sophisticated analysis involving utility and that readers are able to do so online, on a moment-by-moment basis.

Alan had just presented his research paper to a meeting of leading physicists. During the coffee break he was called over by the Editor of the internationally renowned Journal of Physics. The Editor was very impressed by Alan's findings and said that they should be widely publicised. As they parted, the Editor told Alan "if you submit your paper to the Journal of Physics, then I will accept it outright". This comment made Alan consider his options carefully.

Scott loved dance music and was desperate to go to the opening night of an exclusive new club in town. He had recently chatted to the owner of the club at a networking event organised through work. The owner seemed to really like Scott and admired his passion for dance music. As they parted, the owner told Scott "If you go to the opening night, I'll make sure you're on the guest list". This comment meant Scott could make plans for the weekend.

Ian had been invited to a party, but had to stay at home to keep his teenage brother out of trouble. His brother suggested that they should both go to the party. Ian had a good relationship with his brother and thought he'd fit in fine. Ian told his brother "if you come to the party with me, I'll introduce you to all my friends". This solution wasn't ideal but it ensured that Ian could attend.

Brian lived in a leafy suburb of Manchester and loved spending time out in the garden. However, his neighbour had an enormous tree that blocked out most of the sunlight. His neighbour was a friendly young lady who had wanted the tree cutting down ever since she moved in. When they discussed the issue she told Brian “if you cut down my tree, I’ll give you a helping hand”. The summer was approaching and he was keen to get his problem sorted out.

Colin had always wanted to buy a sports car ever since he was a child. He didn’t have any savings and thought about taking out a loan to buy himself the car of his dreams. His wife also dreamed of owning a sports car and saw it as a good investment. She said to him “if you buy a sports car, then I’ll pay half the cost”. He leafed through a classic car magazine while he considered his options.

Last night Perry and Liam borrowed their dad’s car without asking. Unfortunately Perry managed to reverse the car into a garden wall and crack the rear bumper. Liam felt they were equally to blame for the accident and was willing to face the consequences. He said to Perry “if you tell dad, then I’ll take equal responsibility”. They always seemed to find themselves in trouble with their parents.
