ABSTRACT: Deep ultraviolet (DUV) photodetectors have wide-range applications in satellite communications, air purification and missile-plume detection. However, the critical barriers for the currently available wide-bandgap semiconductors films based DUV photodetectors are their low efficiency, complicated processes, and lattice mismatch with substrate. Quantum dots (QDs) devices prepared using solution based methods can solve these problems. However, so far, there are no any reports on

1
2
3
4 photovoltaic-type DUV photodetector using QDs. In this study, we propose a novel
5
6 methodology to construct a hybrid Zero-/Two-dimensional DUV photodetector (p-type
7
8 graphene/ZnS QDs/4H-SiC) with photovoltaic characteristics. The device exhibits
9
10 excellent selectivity for DUV light and has an ultra-fast response speed (rise time: 28
11
12 μs and decay time: 0.75 ms), which are much better than those reported for conventional
13
14 photoconductive photodetectors.

Introduction

Owing to strong absorption by ozone and the atmosphere, deep ultraviolet (DUV) light (200-280 nm) in sunlight is difficult to reach the surface of earth. Therefore, DUV photodetectors are mainly used in satellite, missile-plume detection, and secure communications.¹⁻⁵ So far, the sensitive layer materials for the conventional DUV photodetectors are the wide bandgap semiconductor films, such as AlGaIn,⁶ Ga₂O₃,⁷⁻¹¹ and MgZnO.¹² Unfortunately, the preparation processes for these films are often complicated and expensive, and the lattice mismatch between film and the substrate is often a concern for its application.

To solve these problems, solution-processable semiconductor QDs could be used as the sensing layers for the DUV detection. They have the advantages of low cost, high absorption efficiency, tunable bandgaps and compatibility with multiple substrates (including those flexible ones). Due to these, they have already been applied for photodetector.¹³⁻¹⁵ In recent years, QDs photodetectors based on ZnO,^{16, 17} perovskite,^{18, 19} and PbS^{20, 21} has been extensively studied and these reported photodetectors have extremely high responsivity and switching ratios, demonstrating their great potentials for the photodetector applications. Unfortunately, due to the relatively narrow bandgaps of these materials, these QDs-based photodetectors commonly work at the wavelengths between long-range ultraviolet (300-400 nm) and NIR (near infrared) regions. Only a few DUV photodetectors based on QDs have been reported.^{22, 23} Therefore, there is an urgent need to search for new types of semiconductor QD materials which are sensitive to the DUV.

1
2
3
4 The Bohr exciton radius of ZnS QDs is ~ 2.5 nm, which is much smaller than the
5
6 above mention semiconductors. Based on the quantum confinement effect, the bandgap
7
8 of ZnS QDs can be further increased by reducing their crystal sizes, which make them
9
10 much more sensitive to the DUV.^{24, 25} At the same time, they have higher exciton
11
12 binding energy values (~ 40 meV) and better thermal stability.²⁶ Therefore, ZnS QDs
13
14 could be an excellent DUV sensitive material and can be used in the DUV
15
16 photodetectors.
17
18
19
20

21
22 In this study, we designed and fabricated a DUV photodetector using the ZnS QDs
23
24 with a PIN structure (p-type graphene/ZnS QDs/4H-SiC). Measurement results showed
25
26 that the device exhibits extremely high spectral selectivity in the DUV region. The open
27
28 circuit voltage is approximately 1.1 V at $780 \mu\text{W}/\text{cm}^2$. Under 0V bias, the device has a
29
30 responsivity of 0.29 mA/W and an EQE of 1.36%. Under pulsed light, the rise and
31
32 decay time of the device are 28 μs and 0.75 ms respectively, which can meet the needs
33
34 of practical applications. We believe that this design methodology not only provides a
35
36 promising solution for the application of QDs in the field of DUV photodetector, but
37
38 also opens up a new application strategy for application of composites of zero-
39
40 dimensional (0D) and two-dimensional (2D) nanomaterials.

47 48 **Results and Discussions**

49
50 Schematic illustration of synthesis procedure of ZnS QDs is shown in Figure 1a.
51
52 High-angle Annular Dark-field Scanning Transmission Electron Microscopy
53
54 (HAADF-STEM) image of ZnS QDs is shown in Figure 1b and Figure S1b is the
55
56 distribution of particle sizes. The grain size of the sample is found to be 1.8~2.7 nm.
57
58
59
60

1
2
3
4 Figure S1a is another enlarged HAADF-STEM image while Figure S1 c and d are the
5
6 corresponding energy dispersive X-ray spectroscopy (EDS) mapping images. Figure 1c
7
8 shows the UV-visible absorption spectrum of ZnS QDs. A strong exciton absorption
9
10 peak is located at 265 nm and the corresponding bandgap is 4.68 eV. Compared with
11
12 band gap value of the bulk ZnS (e.g., 3.7 eV), ZnS QDs show a blue shift of the bandgap
13
14 value due to the quantum confinement effect. Figure 1d shows the X-ray diffraction
15
16 (XRD) pattern of the synthesized ZnS QDs. All the diffraction peaks are corresponding
17
18 to the zinc blende structure of ZnS (JCPD No. 05-0566). The average grain size D of
19
20 the prepared sample can be calculated according to the Debye-Scherrer formula,
21
22
23
24
25

$$D = 0.89 \lambda / \beta \cos\theta \quad (1)$$

26
27 where D is the average grain size of the particles, λ is the wavelength of the X-ray, β is
28
29 the full width of the half-maximum of the diffraction peak, and θ is the diffraction angle.
30
31
32
33
34
35 The calculated average grain size of the synthesized ZnS QD is about 2.5 nm, which is
36
37 consistent with HAADF-STEM results. Figures 1e and f show the high-resolution X-
38
39 ray Photoelectron Spectroscopy (XPS) of Zn 2p and S 2p, respectively. The peaks of
40
41 1022.35 and 1044.97 eV are corresponding to the Zn^{2+} of the Zn 2p 3/2 and Zn 2p1/2,
42
43 respectively.²⁷ The binding energy of S 2p is at 161.9 eV, suggesting the presence of
44
45 S^{2-} ion.²⁸ And the corresponding XPS survey spectrum of ZnS QDs is shown in Figure
46
47
48
49
50
51
52
53
54
55
56
57
58
59
60
S2. The results of XPS indicate that no impurities are present in the synthesized ZnS
QDs.

56 The schematic illustration of the preparation process and the image of the DUV
57
58 photodetector (p-type graphene/ZnS QDs/4H-SiC) are shown in Figure 2a and S3. It

1
2
3
4 consists of Ti/Au electrode, transferred p-type graphene, ZnS QDs film, single crystal
5
6 4H-SiC substrate and hot-melt In. Here, the single-layer p-type graphene (p-Gr), ZnS
7
8 QDs film and 4H-SiC single crystal substrate are constructed into a PIN junction.
9
10 Among them, ZnS QDs are also used as a deep ultraviolet sensitive layer due to its
11
12 ultra-wide bandgap (4.68 eV). The 4H-SiC single crystal substrate is used as n-type
13
14 layer. Meanwhile, p-Gr is not only served as a DUV transparent electrode to collect
15
16 photo-generated carriers, but also formed as a PIN structure, together with a sensitive
17
18 layer and a substrate layer. In order to determine the presence of graphene, the Raman
19
20 spectra of the p-Gr is shown in Figure 2c. The D, G and 2D bands of graphene are
21
22 centered at 1343, 1589 and 2860 cm^{-1} , respectively. A cross-sectional scanning electron
23
24 microscope (SEM) image shown in Figure 2b confirms that the effective thickness of
25
26 the ZnS QDs film was about 315 nm. The surface morphology image of the ZnS QDs
27
28 film with different magnifications are shown in Figures S4 a and b. It can be seen that
29
30 there are micro-cracks on the surface of the ZnS QDs film, which is caused by the
31
32 substitution of long oleylamines ligands by short inorganic ligands during the process
33
34 of ligand exchange.²⁹ The I-V characteristic curve of the device in dark is shown in
35
36 Figure 2d. The device exhibits an excellent rectification characteristic, which is
37
38 attributed to the PIN-type photodiode formed by the p-type graphene, ZnS QDs film
39
40 and 4H-SiC substrate. In dark state, the forward current of the device is 55.64 nA at
41
42 3V, and the rectifying ratio is 43 compared with reverse current at -3V. The absorption
43
44 spectrum of the as-synthesized ZnS QDs , those aged for 5 days in air and ZnS QDs
45
46 film after ligand exchange were shown in Figure S5. The absorption spectrum of the
47
48
49
50
51

53
54
55
56
57
58
59
60

1
2
3
4 synthesized ZnS QDs was unchanged after they storage in air for 5 days. This suggests
5
6 the excellent stability of synthesized ZnS QDs. Compared with the synthesized ZnS
7
8 QDs, the exciton peaks of ZnS QDs film show a red shift after ligand exchange, which
9
10 is due to the improved coupling between neighboring QDs and enhanced dielectric
11
12 constant of the QDs thin film.³⁰ The current-voltage (I-V) characteristics of the ZnS
13
14 QDs film/4H-SiC DUV photodetector in dark and under DUV condition are shown in
15
16 Figure S6. The I_{photo}/I_{dark} is about 1.6 under 250 nm light illumination with 3V bias. It
17
18 did not show rectification characteristics compared to p-Gr/ZnS QDs film/4H-SiC
19
20 heterostructures.
21
22
23
24
25

26
27 In order to study the performance of this PIN device based on the ZnS QDs, a
28
29 series of DUV tests were performed. Figure 3a shows the I-V characteristics of the
30
31 device under the irradiation of 250 nm DUV light (red spheres) and that under dark
32
33 state (black spheres). The device exhibits an open circuit voltage of approximately 1.1
34
35 V, and the electromotive force of p-Gr higher than the 4H-SiC. Figure 3b shows the
36
37 corresponding time-voltage (T-V) curve. The open circuit voltage of the device
38
39 maintains a good stability under the DUV light illumination. Figure 3c shows the
40
41 relationship between the open circuit voltage of the device and the light intensity
42
43 illuminated by a 250 nm DUV light source. The open circuit voltage is about 0.49 mV
44
45 when the optical power density is 24 $\mu\text{W}/\text{cm}^2$. It can be seen that as the optical power
46
47 increases, the open circuit voltage gradually increases and tends to be saturated. When
48
49 the optical power is increase to 1.9 mW/cm^2 , the open circuit voltage of the device
50
51 reaches to 1.22 V.
52
53
54
55
56
57
58
59
60

1
2
3
4 To further understand the performance of the DUV detector based on the ZnS QDs,
5
6 we measured its current switching behavior at 0 V bias. As shown in Figure 3d, the
7
8 current can effectively switch continuously, when the light source switches periodically.
9
10 This is indicating that the detector has extremely high response speed and excellent
11
12 repeatability. This is due to the fact that the device can work based on the photovoltaic
13
14 effect. In this device, a built-in electric field will form in ZnS QDs film. Under 250 nm
15
16 LED illumination, photogenerated e-h pairs are generated by ZnS QDs film and quickly
17
18 separated by the built-in electric field, moving from PIN (p-type graphene/ZnS
19
20 QDs/4H-SiC) heterojunction to electrode. Therefore, the photocurrent is produced
21
22 without external bias. The photocurrent of the device is stable at 7 nA with a light
23
24 intensity of 191 $\mu\text{W}/\text{cm}^2$ under a 250 nm LED illumination, while the current drops to
25
26 0.17 nA under the dark state (the switching ratio is approximately 44). Figure 3e shows
27
28 the dependence of photocurrent on the incident light intensity, which is another
29
30 important characteristic of the device. By switching the 250 nm LED on and off at 5
31
32 second intervals under the light illumination in a range of 155 to 184 $\mu\text{W}/\text{cm}^2$, the
33
34 device exhibits a stable periodic response with the switching of the 250 nm LED light
35
36 at a bias of 0 V, and the photocurrent increases as the incident light intensity increases.
37
38 Figure 3f shows the quantitative relationship between the photocurrent extracted and
39
40 the intensity of the incident light obtained from Figure 3e. It is observable that the
41
42 photocurrent exhibits a power-law dependence on the light intensity with an index of
43
44 0.73 ($I_p = P^{0.73}$), and this non-integer index is associated with the trap state of the ZnS
45
46 QDs film.
47
48
49
50
51
52
53
54
55
56
57
58
59
60

The performance of this DUV photodetector can be quantitatively evaluated by calculating the responsivity (R) and specific detection rate (D^*) of the DUV photodetector, which can be calculated by:^{31, 32}

$$R = \frac{I_p - I_D}{P} \quad (2)$$

$$D^* = \frac{(I_p - I_D) \sqrt{A}}{P \sqrt{2eI_D}} \quad (3)$$

where I_p is the photocurrent, I_D is the dark current, P is the intensity of light incident on the device, A is the effective area of the sensitive area, and e is the electron charge.

From the above two equations, the optical response of the device at 0V bias can be calculated to be 0.29 mA/W, and the obtained specific detection rate is 1.41×10^{10} jones.

In addition, the EQE of the device can be calculated by:^{33, 34}

$$EQE = \frac{hcR}{e\lambda} \quad (4)$$

where h is Planck constant, c is the velocity of the incident light, e is the charge, and λ is the wavelength of the incident light. It can be calculated that the EQE of the device under $155 \mu\text{W}/\text{cm}^2$ light density at a wavelength of 250 nm is 1.36%. The above results, suggest that this DUV photodetector has a high responsivity without external bias.

Temporal-response speed is another important parameter of photodetectors, which demonstrates the ability of the device to respond to high frequency optical signals. Here, we used a 193 nm pulsed laser as the ultra-fast-changing UV light signal and measured the time responses of the photovoltaic device, as shown in Figure 4a. The time-dependent photo-response period signal is shown in Figure 4b, and the device can reproduce the optical pulse signal very well. The rise time (T_{90}) is defined as the time

1
2
3
4 spent by photocurrent approaching 90% of the maximum photocurrent, and the decay
5
6 time (T_{10}) is considered as the time photocurrent needs to get back to 10% of the
7
8 maximum photocurrent.¹⁶ Then, the rise and decay time of the device can be analyzed
9
10 by extending the coordinate axis. It can be seen that the rise and decay time of this DUV
11
12 photodetector are 28 μ s and 0.75 ms, respectively (Figure 4c, 4d), which indicate that
13
14 this device has the ability to follow the rapidly changed optical signals. Table 1
15
16 summarizes the reported performance of photodetectors based on different QDs from
17
18 the literature. Compared with most of the other QDs photodetectors, present
19
20 photodetector based on ZnS QDs shows extremely fast response speeds. We believe
21
22 that the ultrafast response speed of such a device is attributed to the built-in electric
23
24 field in p-Gr/ZnS QDs film/4H-SiC, which allows photogenerated carriers to be rapidly
25
26 separated.
27
28
29
30
31
32
33

34
35 Figure 5a shows the responsivity spectrum of the device without bias (dark circle).
36
37 At a wavelength of 250 nm, the responsivity is 0.29 mA/W, indicating that the
38
39 photodetector can be used to detect the DUV without any external bias. When the
40
41 incident wavelengths are changed to 280 nm and 310 nm, the responsivity values of the
42
43 device are only 0.036 mA/W and 0.0068 mA/W, respectively. This is suggesting good
44
45 selectivity of the photodetector for the DUV. In addition, the device has a DUV-UVA
46
47 injection ratio [$R(250\text{ nm})/R(365\text{ nm})$] of 3.89×10^2 , further demonstrating its excellent
48
49 selectivity for the DUV.
50
51
52
53
54

55
56 The energy band diagram of the device is shown in Figure 5b. At 0V bias, a built-
57
58 in electric field is formed at the interface between the p-Gr and the ZnS QDs film, and
59
60

1
2
3
4 its direction is directed from ZnS QDs film to p-Gr. The exciton peak of the ZnS QDs
5
6 film is located at 270 nm. Hence, under the illumination of 250 nm UV light,
7
8 photogenerated electron hole pairs produce in ZnS QDs film. When the 250 nm DUV
9
10 light is incident on the surface of the ZnS QDs film, the electron-hole pairs generated
11
12 from the ZnS QDs film are separated by the built-in electric field, where the holes drift
13
14 towards the graphene surface, whereas the electrons move towards 4H-SiC. For this
15
16 vertical-structure photovoltaic detector, its carrier transit time is much shorter than the
17
18 recombination time of the electron and hole. This enables a relatively fast DUV
19
20 photoresponse time.³⁵ Under 250 nm UV light illumination, the open circuit voltage of
21
22 the device is about 1.2 V at 1.9 mW/cm², forming a photovoltaic based ultraviolet
23
24 photodetector.
25
26
27
28
29
30
31
32
33
34

35 CONCLUSION

36
37
38 In summary, a PIN DUV photovoltaic-type detector based on ZnS QDs was
39
40 successfully designed and tested, in which ZnS QDs were deposited on the 4H-SiC
41
42 substrate using spin coating. It is worth noting that this PIN photodetector based on ZnS
43
44 QDs exhibited an outstanding spectral selectivity for the DUV. Under 250 nm light
45
46 illumination of 184 $\mu\text{W}/\text{cm}^2$, the responsivity of the device was 0.29 mA/W without
47
48 external bias. In addition, the device shows an ultrafast rise and decay time (28 μs / 0.75
49
50 ms) under 193 nm pulsed laser illumination. This work not only lays a foundation for
51
52 the application of QDs in the field for DUV detection, but also paves a new way to
53
54 composite 2D and 0D nanomaterials.
55
56
57
58
59
60

METHODS

Synthesis of ZnS Quantum Dots. The ZnS QDs were synthesized using a modified heat-up method.³⁶ 4.41 g of zinc stearate (ZnSt_2), 0.225 g of thioacetamide (TAA), 6 ml of oleylamine(OLA) and 50 mL of octadecene (ODE) were added into a 100 mL volume three-necked flask. The flask was degassed under the vacuum at room temperature and heated to 140 °C for 1 h under nitrogen. After the reaction was completed, the solution was quickly cooled down to room temperature. Further, the precipitate was washed 2-3 times using hexane, and ethanol and then dispersed for use in octane.

Device preparation. The single crystals of 4H-SiC were purchase from KMT corporation, China. The film was deposited using a spin-coating method as described below. Briefly, 40 μL of ZnS QD solution was deposited on the surface of 4H-SiC by spin-coating at 3000 rpm for 30 seconds. The obtained ZnS QDs film was then immersed in a hexadecyltrimethylammonium bromide (CTAB) solution (10 mg/mL in anhydrous methanol) for 45 seconds. The CTAB solution was spun at a speed of 3000 rpm for 30 s. Lastly, the film was washed three times with anhydrous methanol. After repeating the above process for three times, a ZnS QDs film with a given thickness was obtained on 4H-SiC. After depositing the ZnS QDs film, the target size graphene was constructed on the surface of the ZnS QDs film using a wet transfer method. Then, 50 nm Ti and 50 nm gold were deposited on the graphene edge using a thermal evaporation method. Finally, we used hot-melt indium (In) as the electrode on the side of the 4H-

1
2
3
4 SiC.
5

6 **Characterization and Measurements.** The X-ray diffraction (XRD) measurement
7 was performed using an X-ray diffractometer (MAXima_XXRD-7000, Shimadzu,
8 Japan). The shape and size of ZnS QDs was characterized using a Titan Cubed Themis
9 G2 300. Morphologies of the ZnS QDs films were obtained using a FEI model SIRION
10 200 microscope. The absorption spectra of the ZnS QDs were recorded using a UV-vis-
11 NIR spectrophotometer (UV 3600 Plus, Japan). XPS measurements were performed
12 using a Thermo-VG Scientific ESCALab 250 microprobe. Photodetector device
13 performance was measured using the SourceMeter Keithley 2636B. Lighting was
14 generated through an Agilent source controlled a 250 nm semiconductor light-emitting
15 diode (LED). The spectral response was measured by LEDs or lasers. In the high-speed
16 photoresponse test shown in Figure 4, an ArF laser with a wavelength of 193 nm was
17 used as a pulse light source, and an oscilloscope (Keysight DSOS604A) was used to
18 acquire a high-speed voltage signal.

FIGURES

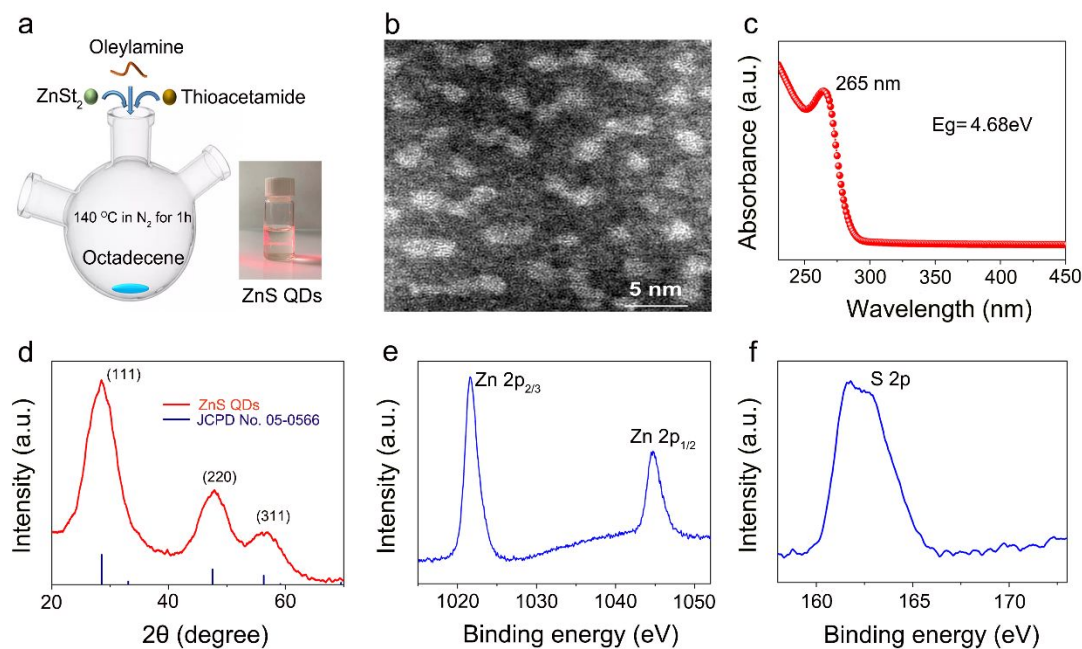

Figure 1. (a) Schematic illustration of synthesis procedure of ZnS QDs. (b) HAADF-STEM images of the ZnS QDs. (c) UV-vis absorption spectrum of the ZnS QDs (d) XRD pattern of ZnS QDs. XPS spectra of (e) Zn 2p and (f) S 2p of the ZnS QDs.

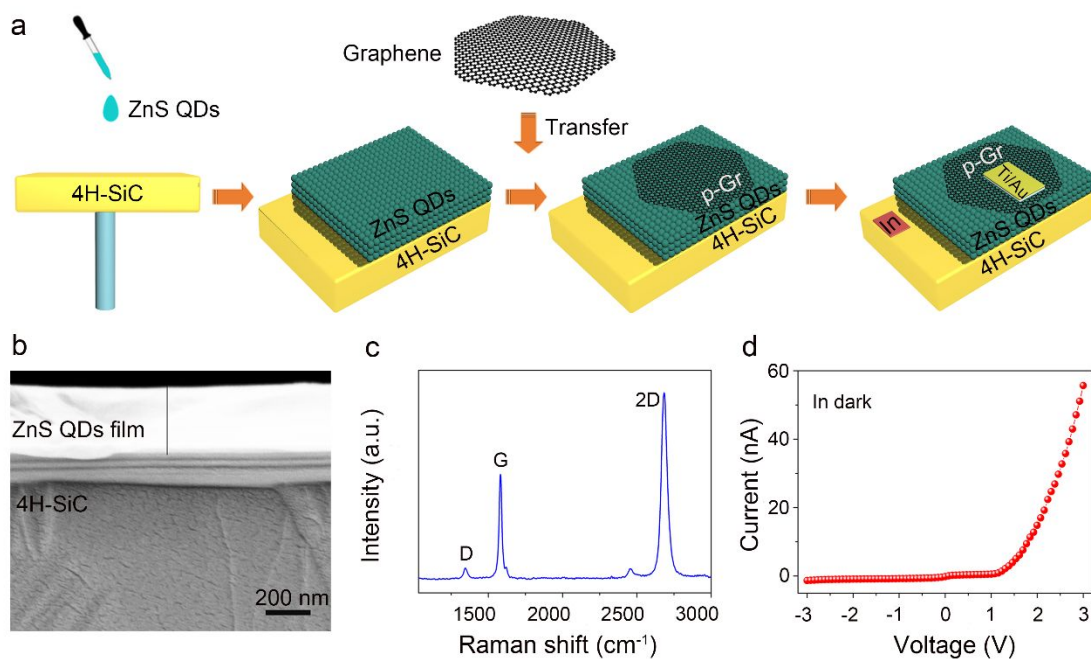

Figure 2. (a) Fabrication procedure of the DUV photodetector (p-type graphene/ZnS QDs/4H-SiC). (b) Cross-sectional SEM image of the device. (c) The Raman spectra of the Graphene (d) I–V curves of the device in dark.

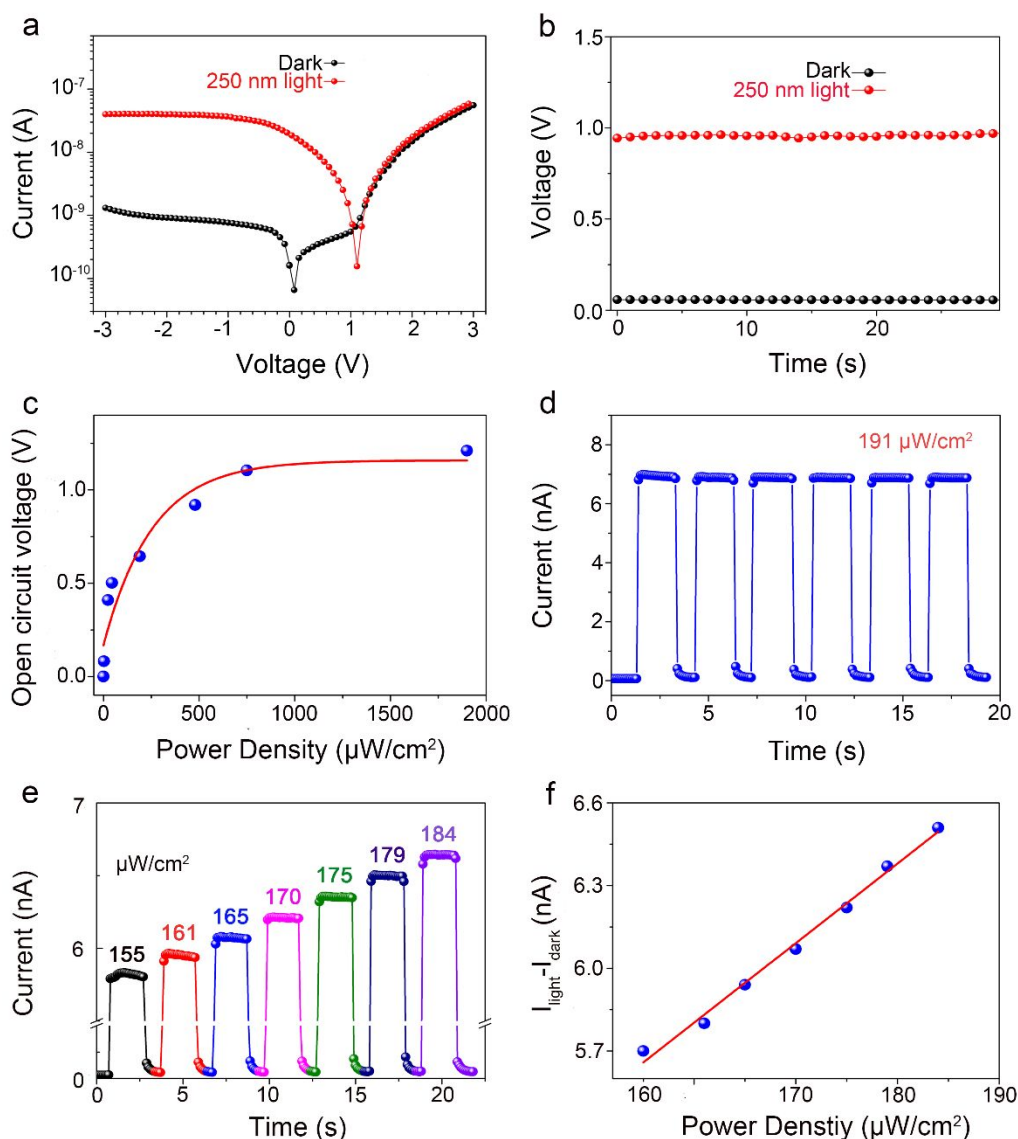

Figure 3. DUV photovoltaic testing (a) I–V characteristics of the device under dark conditions and illuminated with 250 nm UV light. (b) Voltage-Time output results of the device under dark and illuminated with 250 nm UV light. (c) The dependence of open circuit voltage on UV light intensity. (d) Time-resolved DUV photoresponse of the device under 250 nm DUV light illumination ($191 \mu\text{W}/\text{cm}^2$) without bias. (e) Light intensity dependent photoresponse of the device irradiated by 250 nm LED without bias. (f) The dependence of photocurrent on light intensity without bias.

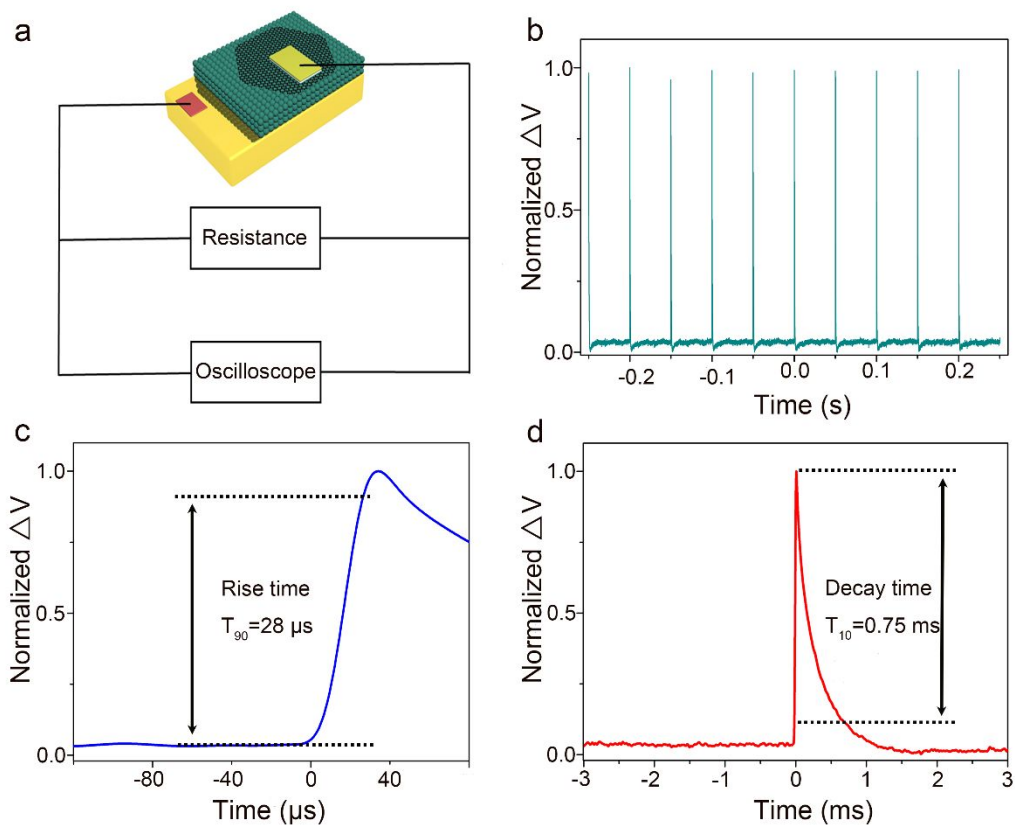

Figure 4. (a) Schematic diagram of the photovoltaic response under 193 nm light with a nanosecond pulse. (b) Voltage output signal of the device generated under 10 equal interval pulses. (c) Relationship between rise time (μs) and normalized ΔV . (d). Relationship between decay time (ms) and normalized ΔV .

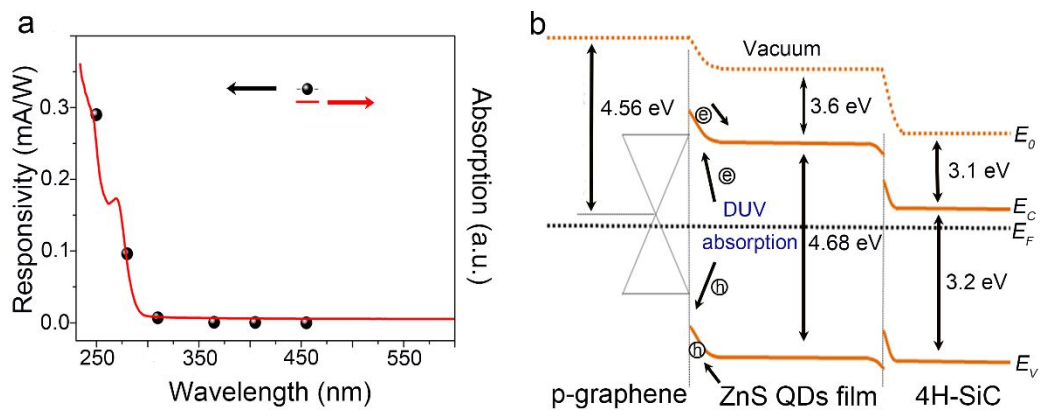

Figure 5. (a) Responsivity spectrum of the device at different LED wavelengths (dark circle) and the absorption of the ZnS film (red line). (b) Energy band diagram of p-Gr/ZnS QDs film/ 4H-SiC heterostructure.

Table 1. Comparison of the characteristic photoresponse parameters of the photodetector based on QDs

Materials	Wavelength	Bias	Rise time	Decay time	Ref.
ZnS QDs	254 nm	40 V	0.35 s	0.07 s	22
ZnO QDs	224.3 nm	5 V	<0.08 s	<0.08 s	23
ZnO QDs/G	330 nm	10 V	5 s	85.1 s	37
Graphene QDs	254 nm	5 V	0.064 s	0.023 s	38
ZnO QDs	325 nm	5 V	0.8 s	0.5 s	39
Graphene QDs /ZnO Nanorods	365 nm	2 V	2.14 s	0.91 s	40
ZnO QDs/Zn ₂ SnO ₄ Nanowire	300 nm	0.1 V	0.047 s	-	41
p-Gr/ZnS QDs/4H-SiC	250 nm	0 V	0.000028 s	0.00075 s	This work
